Table 1: Spectral evidence: large-E fits of $\log D$ or $\log \lvert Q \rvert$ (dominant Frobenius exponent) for the three operators, point A (all points in the supplementary table). Class: W = WKB coefficient $-\int s_K$ (predicted); R = non-WKB term registered before the data; S = non-WKB term whose power was sealed, coefficient fitted; H = post-hoc term; F = fitted free (grade 1); U = resonant finite part, not identified; * = undetermined (error estimate exceeds the value). d = agreement digits $-\log_{10} \lvert \text{fit} - \text{pred} \rvert / \lvert \text{pred} \rvert$ (for a zero prediction the absolute fit is shown); e = error-estimate digits, $-\log_{10} \varepsilon / \lvert \text{fit} \rvert$, with ε the largest spread over two shifted fit windows, two basis truncations and, where archived, 60- vs 120-digit data. All predicted rows agree within 10ε.
